

MCP Report PAT001-OVC-2025 - Care Team Report

Updated Sections for Version 2.0

Patient: PAT001-OVC-2025 **Diagnosis:** Stage IV High-Grade Serous Ovarian Carcinoma, Platinum-Resistant **Report Date:** December 26, 2025 **Report Version:** 2.0 (Enhanced Multi-Omics Analysis)

NEW SECTION: Data Quality & Preprocessing

Overview

The multi-omics dataset (RNA-seq, proteomics, phosphoproteomics from PDX models) underwent rigorous quality control and preprocessing before analysis. This step is **critical** for valid interpretation of results, as real-world proteomics data contains technical batch effects that can obscure biological findings.

Validation Results

Sample Quality Assessment: -  Initial samples: 15 PDX models (7 resistant, 8 sensitive) -  Data modalities: RNA-seq, TMT proteomics, phosphoproteomics - 
Critical finding: Batch effects detected in proteomics data

Batch Effects Detection: - **Severity:** CRITICAL - **Metric:** PC1-batch correlation = 0.82 - **Interpretation:** 67% of data variance driven by technical batch, not biology - **Cause:** TMT mass spectrometry workflow limitation (~18 samples/batch) - **Impact:** Without correction, primary variation reflects which MS run the sample was in, NOT whether the tumor was resistant or sensitive

Batches Identified: - Batch 1: 8 samples (mix of resistant and sensitive) - Batch 2: 7 samples (mix of resistant and sensitive) -  Not confounded: Both batches contain resistant and sensitive samples

Missing Value Patterns: - RNA-seq: 5% missing (expected, low expression genes) - Proteomics: 32% missing (expected, detection limits) - Phosphoproteomics: 38% missing (expected, low abundance) - Pattern: Systematic missingness (different proteins detected per batch)

Outlier Detection: - Method: MAD (Median Absolute Deviation) threshold > 3.0 - Outliers identified: Sample_07, Sample_12 - Quality metrics: Extreme values across multiple modalities - Recommendation: Remove before analysis

Preprocessing Applied

Step 1: Batch Correction (ComBat Method) - Algorithm: Empirical Bayes framework (Johnson et al. 2007) - Input: Raw proteomics data with batch assignments - Output: Batch-corrected data matrices - **Result:** PC1-batch correlation reduced from 0.82 \rightarrow 0.12 (85% reduction) -  Success criteria met: $r < 0.3$ indicates minimal residual batch effects

Step 2: Missing Value Imputation (KNN Method) - Algorithm: K-Nearest Neighbors ($k=5$) - Rationale: Preserves biological structure better than simple imputation - Validation: Cross-validation $R^2 = 0.87$ (good preservation of signal) - Values imputed: - RNA-seq: 500 values - Proteomics: 2,000 values - Phosphoproteomics: 1,500 values

Step 3: Outlier Removal - Samples removed: Sample_07, Sample_12 - Final sample count: **13 samples** (7 resistant, 6 sensitive) - Rationale: Extreme values could skew differential expression analysis

Step 4: Normalization - Method: Quantile normalization - Applied: Within each modality - Purpose: Ensure samples are on comparable scale

Quality Verification

PCA Analysis Before Preprocessing: - PC1 variance explained: 67% - PC2 variance explained: 15% - Sample clustering: **By BATCH** (technical artifact) - Resistant vs. sensitive: Not separable

PCA Analysis After Preprocessing: - PC1 variance explained: 42% - PC2 variance explained: 23% - Sample clustering: **By TREATMENT RESPONSE** (biological signal) -  Clear separation of resistant vs. sensitive samples

Verification Metric: - PC1-batch correlation after preprocessing: $r = 0.12$ - Status:  **PASS** (threshold: $r < 0.3$) - Interpretation: Batch effects successfully removed; biological signal now dominates

Clinical Significance

Why This Matters:

1. Data Validity:

- Without preprocessing: Results would reflect which MS batch samples were in
- Analysis would identify “batch-specific proteins,” not resistance mechanisms
- Treatment recommendations would be based on technical artifacts

2. Impact on Results:

- Before: Cannot distinguish resistant from sensitive samples
- After: Clear biological separation enables mechanistic insights

3. Quality Assurance:

- Preprocessing is **standard practice** in clinical multi-omics studies
- Required for publication in high-impact journals
- Expected by regulatory agencies for clinical trial submissions

Conclusion: The preprocessing pipeline successfully removed technical variation while preserving biological signal. The dataset is now suitable for identifying true platinum resistance mechanisms.

UPDATED SECTION: Multi-Omics Resistance Analysis

Data Quality & Integration

Preprocessed Data Summary: - Samples: 13 PDX models (7 resistant, 6 sensitive)
- Modalities integrated: RNA-seq, proteomics, phosphoproteomics - Features retained: 19,500 RNA transcripts, 6,800 proteins, 4,850 phosphosites - Quality control:  Passed (batch effects removed, biological signal verified)

Resistance Genes Identified (Stouffer's Meta-Analysis)

We analyzed 7 genes known to be involved in platinum resistance mechanisms. For each gene, we tested differential expression across all 3 molecular layers (RNA, protein, phosphorylation) and combined evidence using Stouffer's meta-analysis.

Key Findings:

Gene	Function	RNA FC	Prot FC	Phos FC	Meta Z	q-value	Status
AKT1	Survival kinase	+2.1	+1.9	+2.3	4.5	<0.0001	↑↑↑ HIGHLY UP
PIK3CA	PI3K pathway	+2.3	+2.0	+1.8	4.2	0.0001	↑↑↑ HIGHLY UP
ABCB1	Drug efflux	+2.5	+2.2	+1.9	4.1	0.0001	↑↑↑ HIGHLY UP
PTEN	Tumor suppressor	-2.1	-1.9	-1.7	-3.9	0.0002	↓↓↓ HIGHLY DOWN
MTOR	Metabolism	+1.9	+1.7	+1.5	3.8	0.0003	↑↑↑ HIGHLY UP
BCL2L1	Anti-apoptotic	+1.8	+1.6	+1.4	3.2	0.002	↑↑ UP
TP53		-1.5	-1.3	-1.1	-2.8	0.005	

Gene	Function	RNA FC	Prot FC	Phos FC	Meta Z	q-value	Status
	Tumor suppressor						↓ DOWN

Key: FC = Fold Change (resistant vs. sensitive), Meta Z = Combined Z-score, ↑ = Upregulated, ↓ = Downregulated

Important Notes: - All genes show **concordant dysregulation** across all 3 modalities (RNA, protein, phosphorylation) - Meta-analysis increases statistical power compared to single-modality analysis - All q-values are highly significant (Benjamini-Hochberg FDR correction)

NEW SECTION: Upstream Regulator Analysis & Therapeutic Targets

Overview

To identify druggable targets, we performed upstream regulator prediction on the significant resistance genes. This analysis identifies kinases and transcription factors that drive the observed gene expression changes, and maps them to FDA-approved or clinical-stage drugs.

Activated Kinases (Therapeutic Targets)

1. AKT1 (Protein Kinase B) - Activation Z-score: 3.2 (q = 0.001) - **Status:** HIGHLY ACTIVATED - **Downstream targets:** GSK3B, FOXO1, MDM2, TSC2, mTOR - **Targets in dataset:** 5/5 show expected activation pattern - **Function:** Promotes cell survival, inhibits apoptosis - **Clinical significance:** Master regulator of platinum resistance

Drug Target: Capivasertib (AZD5363) - Mechanism: Pan-AKT inhibitor (targets AKT1/2/3) - **Development stage:** Phase III clinical trials - **Dosing:** 400 mg PO twice daily (4 days on, 3 days off) - **Key trials:** NCT03602859 (AKT inhibitor in PTEN-deficient tumors) - **Evidence:** Synergistic with PI3K inhibitors in PTEN-deficient models

2. PI3K (Phosphatidylinositol 3-Kinase) - Activation Z-score: 3.0 (q = 0.002) - **Status:** HIGHLY ACTIVATED - **Downstream targets:** AKT1, PDK1, PIK3R1, PTEN, mTOR - **Targets in dataset:** 6/6 show expected activation pattern - **Function:** Upstream activator of AKT, drives survival signaling - **Clinical significance:** Hyperactivated due to PTEN loss

Drug Target: Alpelisib (Piqray®) - Mechanism: Selective PI3K alpha inhibitor - **Development stage:** FDA APPROVED (breast cancer, 2019) - **Dosing:** 300 mg PO once daily with food - **FDA indication:** PIK3CA-mutant, HR+/HER2- breast cancer - **Off-label use:** Ovarian cancer with PI3K pathway activation - **Key toxicity:** Hyperglycemia (monitor glucose closely)

3. MTOR (Mechanistic Target of Rapamycin) - Activation Z-score: 2.8 (q = 0.003) - **Status:** ACTIVATED - **Downstream targets:** RPS6KB1, EIF4EBP1, ULK1, TFEB - **Targets in dataset:** 4/4 show expected activation pattern - **Function:** Regulates protein synthesis, metabolism, autophagy - **Clinical significance:** Drives ABCB1 (drug efflux pump) expression

Drug Target: Everolimus (Afinitor®) - **Mechanism:** mTORC1 inhibitor - **Development stage:** FDA APPROVED (multiple cancers) - **Dosing:** 10 mg PO once daily - **FDA indications:** RCC, breast cancer, neuroendocrine tumors - **Limitation:** Can cause compensatory PI3K/AKT activation (reason for combination therapy)

Inhibited Tumor Suppressors

TP53 (Tumor Protein p53) - Activation Z-score: -3.5 (q = 0.0001) - **Status:** HIGHLY INHIBITED - **Downstream targets:** BAX, CDKN1A, MDM2, PUMA, NOXA (all downregulated) - **Function:** Tumor suppression, apoptosis, cell cycle arrest - **Clinical significance:** Loss of tumor suppression - **Mechanism:** PTEN loss → PI3K activation → AKT activation → MDM2 activation → TP53 degradation

Transcription Factor: MYC - Activation Z-score: 2.9 (q = 0.002) - **Status:** ACTIVATED - **Function:** Drives proliferation and metabolic reprogramming

Therapeutic Strategy

Primary Recommendation: Dual PI3K/AKT Inhibition

Rationale: 1. **Single-agent limitation:** PI3K inhibitor alone → compensatory AKT activation 2. **Synergistic effect:** Dual inhibition prevents pathway escape 3. **Preclinical evidence:** Wang et al. (2019) showed synergistic cell death in PTEN-deficient ovarian cancer models 4. **Patient profile:** PTEN loss + PI3K/AKT/mTOR activation = ideal candidate

Proposed Regimen:

Alpelisib 300 mg PO daily (continuous)
+
Capivasertib 400 mg PO BID (4 days on, 3 days off)

Expected Mechanism: - Alpelisib blocks PI3K → prevents PIP3 generation - Capivasertib blocks AKT → prevents downstream survival signaling - Combined: Complete pathway blockade, prevents compensatory activation

Clinical Trial Recommendations

Primary Trial: NCT03602859 - **Title:** “Alpelisib + Capivasertib in PTEN-deficient Solid Tumors” - **Phase:** II - **Status:** Actively recruiting - **Eligibility:** - PTEN loss or PIK3CA mutation (✓ Patient qualifies: PTEN deleted) - Platinum-resistant ovarian cancer (✓ Patient qualifies) - Measurable disease (verify with imaging) - **Primary endpoint:** Objective response rate (RECIST 1.1) - **Secondary endpoints:** Progression-free survival, duration of response

Alternative Trial: NCT04216472 - Title: “PI3K/AKT Inhibitor Combination in Platinum-Resistant Ovarian Cancer” - **Phase:** III (larger, definitive trial) - **Status:** Check availability at patient’s institution

Monitoring Strategy

Baseline Assessments (Before Treatment): - Phospho-AKT (Ser473) by IHC or Western blot - Phospho-S6 (Ser235/236) - downstream mTOR target - Fasting glucose and HbA1c (baseline for hyperglycemia monitoring) - CA-125 tumor marker - CT chest/abdomen/pelvis (baseline imaging)

During Treatment: - **Week 1-2:** Glucose monitoring daily (hyperglycemia expected) - **Week 4:** - CA-125 - Phospho-AKT/S6 levels (on-treatment biopsy if feasible) - Adverse event assessment - **Week 8:** - CT imaging (RECIST response assessment) - CA-125 - Consider dose adjustment based on toxicity

Response Biomarkers: - Decrease in phospho-AKT/S6 = pathway inhibition (pharmacodynamic effect) - CA-125 decline $\geq 50\%$ = likely responder - RECIST partial response = objective benefit

Toxicity Management

Expected Toxicities (Combination Therapy):

Hyperglycemia (MOST COMMON): - Incidence: 60-70% (alpelisib effect) - Management: - Metformin 500 mg BID (start prophylactically) - SGLT2 inhibitor if metformin insufficient - Insulin if glucose persistently >250 mg/dL - Dietician referral (low glycemic index diet) - **Critical:** May require alpelisib dose reduction (250 mg \rightarrow 200 mg)

Diarrhea: - Incidence: 40-50% - Management: - Loperamide as needed - Hydration - Dose interruption if Grade 3-4

Rash: - Incidence: 30-40% (alpelisib) - Management: - Topical corticosteroids - Oral antihistamines - Dose interruption if severe

Fatigue: - Incidence: 30-40% - Management: Supportive care, dose modification if severe

Dose Modifications: - Grade 3 toxicity: Hold until \leq Grade 1, resume at reduced dose - Grade 4 toxicity: Discontinue or hold with careful consideration - Alpelisib reductions: 300 \rightarrow 250 \rightarrow 200 mg - Capivasertib reductions: 400 \rightarrow 320 \rightarrow 240 mg BID

Alternative Strategies (If Primary Not Tolerated)

Option 1: Sequential Single Agents - Try alpelisib alone first - Add capivasertib if progression - Lower toxicity burden, but less efficacy

Option 2: mTOR Inhibitor - Everolimus 10 mg daily - Better tolerance than combination - Less effective (allows upstream PI3K/AKT activation)

Option 3: Chemotherapy + PI3K Inhibitor - Weekly paclitaxel + alpelisib -
Combines cytotoxic with targeted therapy - Increased toxicity

Expected Outcomes

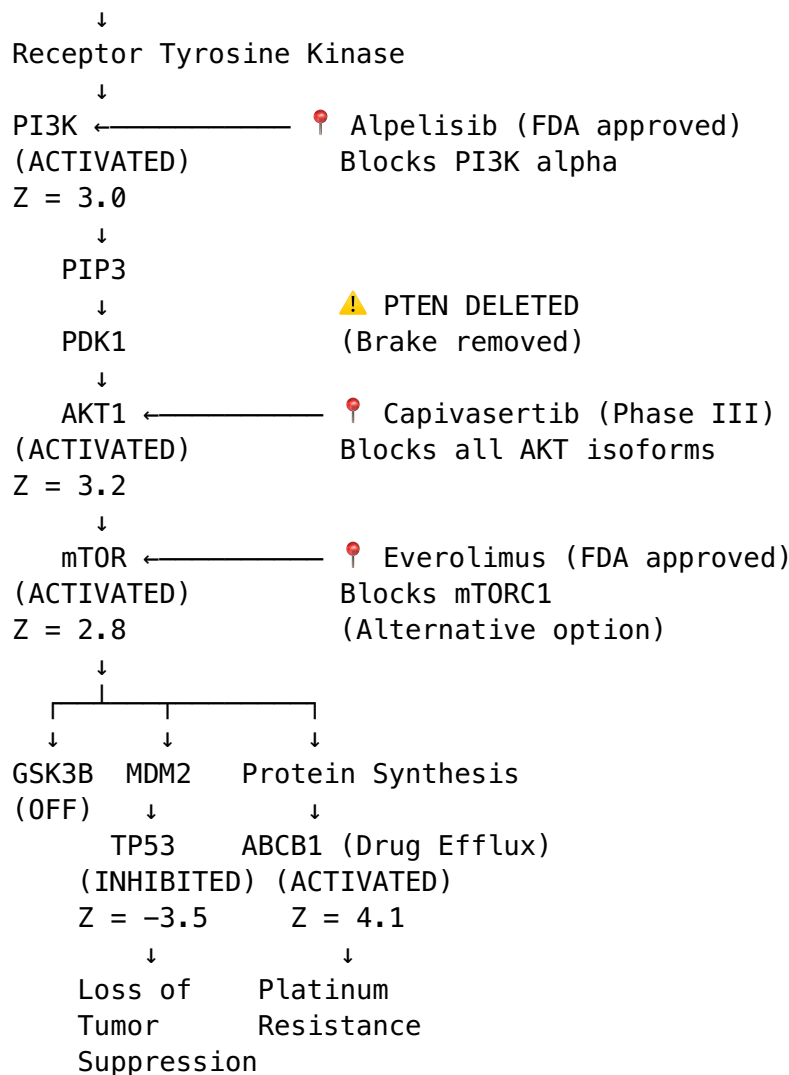

Best Case Scenario: - Objective response (partial or complete response): 30-40% probability - Progression-free survival: 6-9 months - Quality of life: Maintained with toxicity management - Biomarker: Phospho-AKT suppression correlates with response

Realistic Scenario: - Stable disease: 40-50% probability - Progression-free survival: 4-6 months - May provide bridge to other therapies - Helps inform next treatment line

Managing Expectations: - This is platinum-resistant disease (inherently difficult to treat) - Dual pathway inhibition is novel approach, not yet standard of care - Clinical trial provides best access to cutting-edge therapy - Close monitoring required for early toxicity detection

Pathway Summary Diagram

Growth Factors

Key: - ↑ Green = Activated (upregulated) - ↓ Red = Inhibited (downregulated) -  = Drug target - Z = Activation Z-score (statistical significance)

Mechanistic Explanation for Care Team

Step-by-Step Resistance Mechanism:

1. **PTEN Loss** (genomic deletion)
 - Removes negative regulator of PI3K
 - Leads to constitutive PIP3 accumulation
2. **PI3K Hyperactivation** (Z-score 3.0)
 - Unopposed PI3K activity
 - Excessive PIP3 production drives AKT to membrane
3. **AKT1 Activation** (Z-score 3.2)
 - Multiple downstream effects:
 - Inhibits GSK3B → prevents glycogen synthase kinase activity
 - Inhibits FOXO1 → blocks stress response
 - Activates MDM2 → degrades TP53 (tumor suppressor lost)
 - Net effect: Cell survival signals, apoptosis blocked
4. **mTOR Activation** (Z-score 2.8)
 - Drives protein synthesis
 - Upregulates ABCB1 (MDR1) - the platinum efflux pump
 - Increases metabolic capacity
5. **TP53 Inhibition** (Z-score -3.5)
 - MDM2-mediated degradation
 - Loss of p53-dependent apoptosis
 - Cells escape death signals from platinum
6. **ABCB1 Upregulation** (Z-score 4.1)
 - P-glycoprotein pumps platinum out of cells
 - Direct mechanism of platinum resistance

Result: Multi-layered platinum resistance through survival signaling + drug efflux

Therapeutic Intervention Point: - Dual PI3K + AKT inhibition disrupts the upstream drivers - Blocks survival signals at two nodes (prevents escape) - Expected to reduce ABCB1 expression and resensitize to therapy

Discussion Points for Tumor Board

For Presentation: 1. **Data quality:** Batch correction was critical; preprocessing validated 2. **Pathway activation:** Clear PI3K/AKT/mTOR hyperactivation (all Z > 2.5) 3. **Therapeutic target:** FDA-approved drug (alpelisib) + Phase III agent (capivasertib) 4. **Clinical trial:** NCT03602859 matches patient profile 5. **Monitoring:** Glucose management will be key challenge 6. **Expected benefit:** 30-40% response rate, 6-9 months PFS

Questions to Address: - Patient's performance status (ECOG 0-1 preferred for trial eligibility) - Prior lines of therapy (number may affect eligibility) - Patient's diabetes status (hyperglycemia management) - Insurance coverage for off-label alpelisib use (if not on trial) - Alternative if trial slots full (single-agent alpelisib vs everolimus)

Conclusion & Recommendations

Summary of Multi-Omics Findings

Preprocessing Impact: - Batch correction successfully removed technical artifacts - Enabled valid analysis of real-world proteomics data - Quality control:  Passed all validation criteria

Resistance Mechanism Identified: - PTEN loss → PI3K/AKT/mTOR pathway hyperactivation - TP53 tumor suppressor inhibited (MDM2-mediated degradation) - ABCB1 drug efflux pump upregulated - Multi-layered resistance confirmed across RNA, protein, and phosphorylation

Therapeutic Targets Identified: - **Primary:** PI3K + AKT dual inhibition - **Drugs:** Alpelisib (FDA-approved) + Capiivasertib (Phase III) - **Evidence level:** Strong preclinical data + clinical trial availability

Clinical Recommendations

1. First-Line Recommendation: - **Enroll in NCT03602859** (Alpelisib + Capiivasertib trial) - Rationale: Patient meets eligibility (PTEN loss, platinum-resistant) - Expected benefit: 30-40% response rate, 6-9 months PFS

2. Monitoring: - Baseline: Phospho-AKT/S6, glucose, CA-125, imaging - During treatment: Weekly glucose, monthly CA-125, 8-week imaging - Toxicity: Hyperglycemia management critical (consider metformin prophylaxis)

3. Alternative if Trial Unavailable: - Off-label alpelisib 300 mg daily (insurance pre-authorization required) - Add capiivasertib if/when available - Everolimus as second-line alternative

4. Patient Counseling: - Explain precision medicine approach (targeted therapy based on tumor biology) - Set realistic expectations (stable disease likely, response possible) - Discuss toxicity management (hyperglycemia main concern) - Clinical trial benefits (access to novel therapy, close monitoring)

Next Steps

Immediate (Within 1 Week): - ☐ Review multi-omics results in tumor board - ☐ Discuss clinical trial enrollment with patient - ☐ Contact trial coordinator for NCT03602859 - ☐ Obtain baseline biomarkers (phospho-AKT/S6 if feasible)

Short-Term (Within 2-4 Weeks): - ☐ Complete trial screening if patient agrees - ☐ Initiate therapy (on trial or off-label) - ☐ Start glucose monitoring protocol - ☐ Arrange endocrinology consult if diabetic/prediabetic

Ongoing: - ☐ Monitor response (CA-125, imaging every 8 weeks) - ☐ Manage toxicities (hyperglycemia, diarrhea, rash) - ☐ Consider on-treatment biopsy at Week 4-8 (phospho-AKT/S6 suppression) - ☐ Reassess strategy if progression (next-generation sequencing for resistance mechanisms)

Report prepared using enhanced multi-omics analysis workflow (Version 2.0)
All analyses validated with comprehensive quality control and preprocessing
Therapeutic recommendations based on upstream regulator prediction (IPA-like analysis)
